Decoding Living Systems

# From genome to assembly

Sampling

Lib preping

Sequencing

Assembling

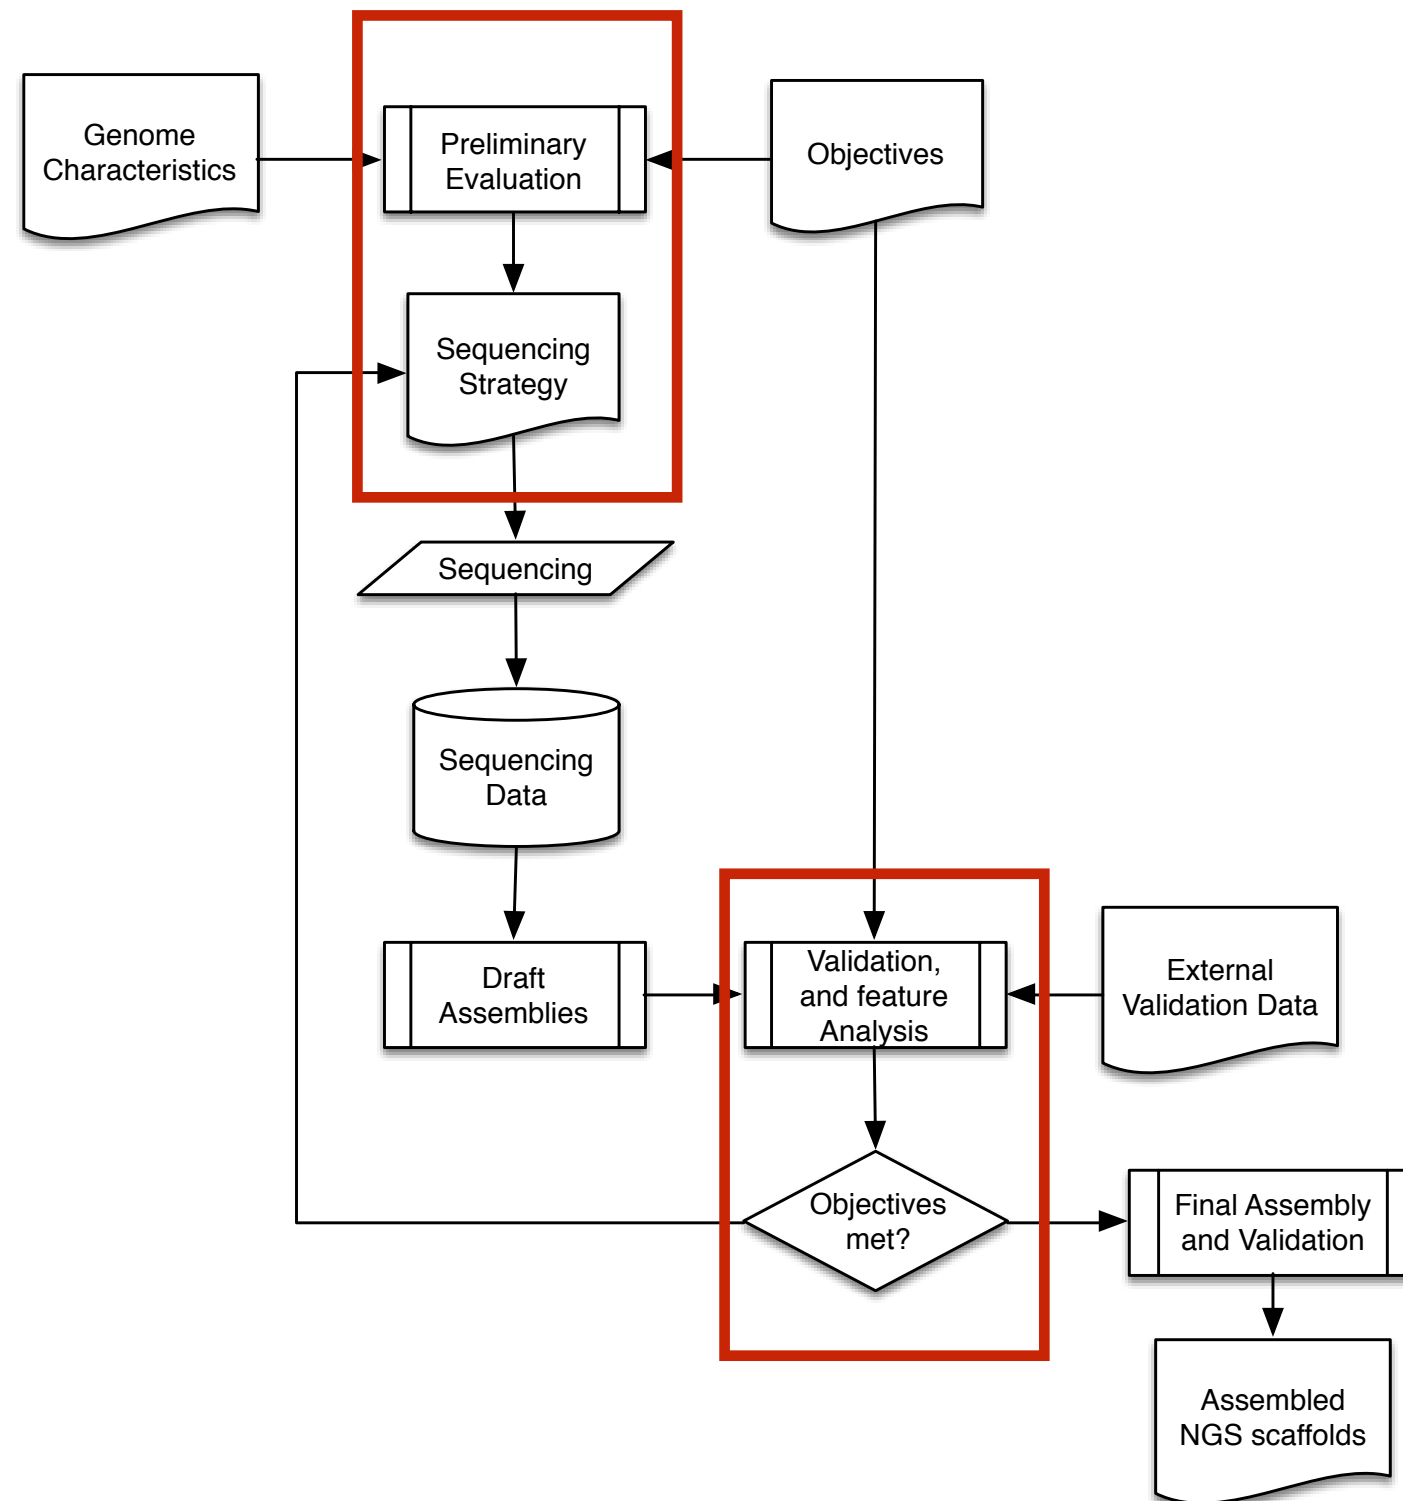

The assembly is a model of the genome.

A tool for hypothesis testing.

Tool to understand the cell/organism/population/ etc.

*Ceci n'est pas une* Genome

# Have an objective and work towards it

**All the information is already present in the experimental results.**

Information can not be created  
if it's not in the sampled data is not recoverable

The assembly process is a reduction exercise

**The assembly is just a probabilistic model of a genome,  
condensing the information from the experimental evidence.**

# Conditions for a correct assembly

**The right *motifs*,  
the correct number of times,  
in correct order and position.**

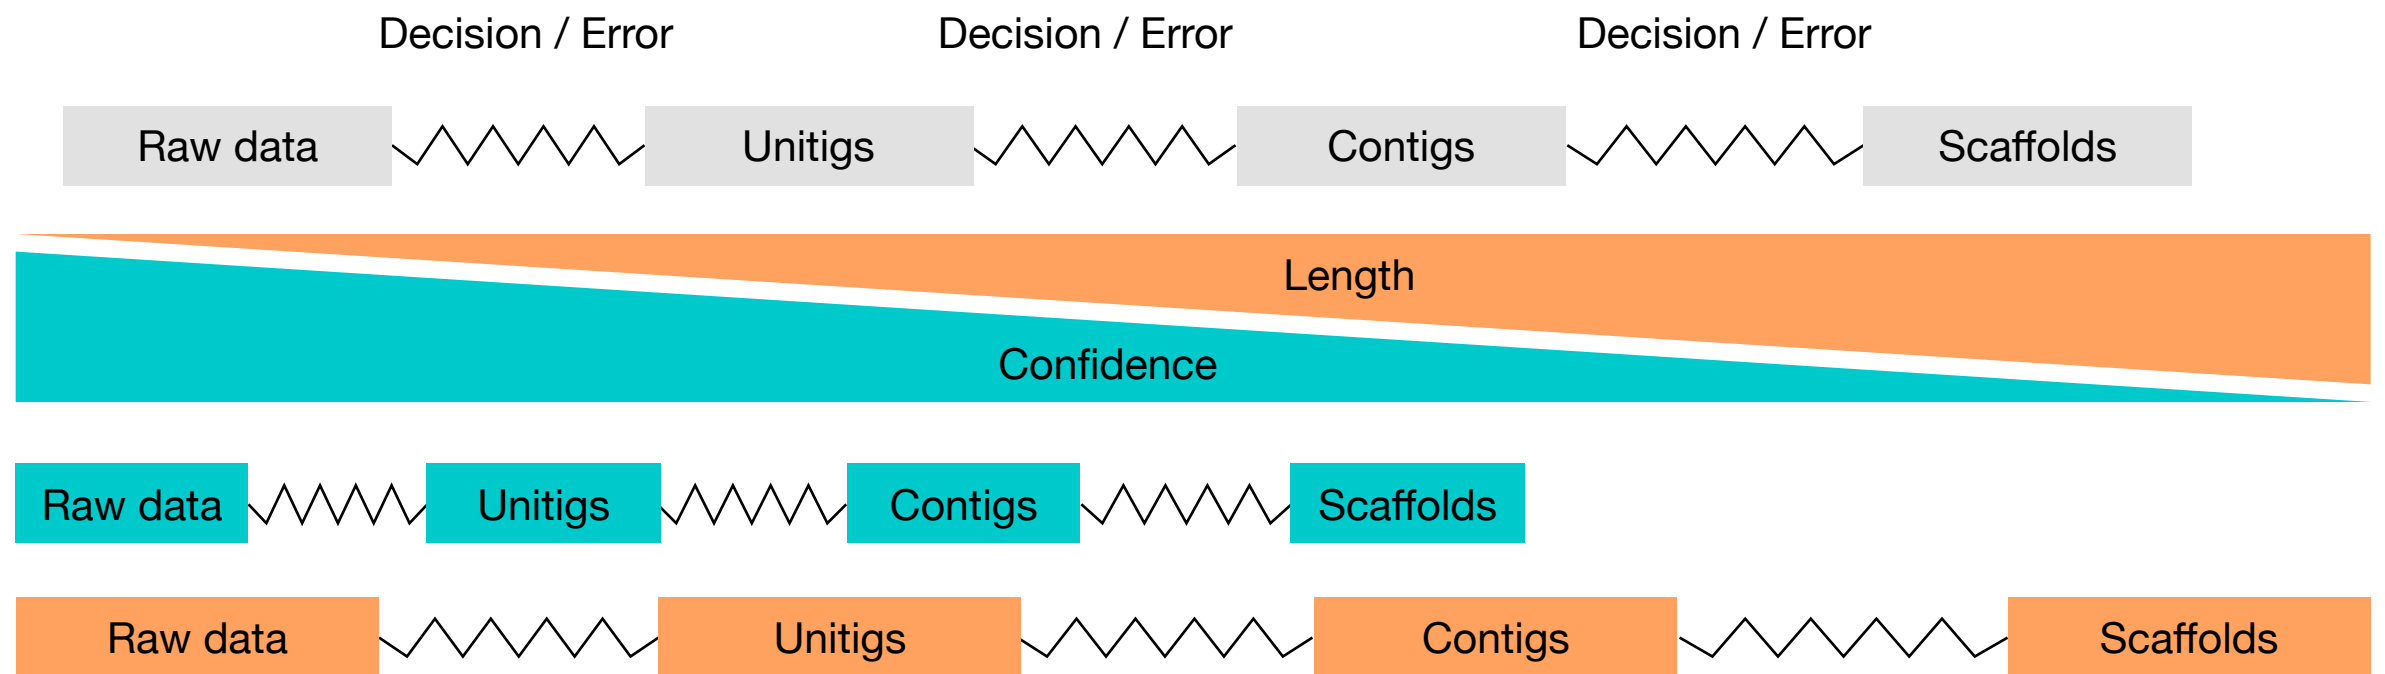

# Graphs, contigs and scaffolds

	Sequence origin	Expected quality	Main quality driver
<b>Unitig</b>	1 element in the graph	Very high	Sequence data, cleanup, overlap detection
<b>Contig</b>	suported chain in the graph	High	+ graph complexity, single-read mapping & entropy
<b>Scaffold</b>	external-link group of contigs	Variable	+ pair reliability, parametrisation

- Graphs: assembler's representation
  - More information
  - Allow some back-tracking
  - Can encode support/ambiguity

# Assembly process and tradeoffs

How much can we stretch the spring while trusting the results

# Approaches for assembly

Paper assembly (?)

Overlap Layout Consensus

De Bruijn Graphs (DBG)

## Overlap Layout Consensus

# Overlap - Layout - Consensus

Finding defining and finding overlaps is key.

The layout can be quite difficult.

The consensus is constructed from the reads.

The method tracks every read.

# Short kmer introduction

The kmers of a sequence are all possible k-size subsequences of a sequence

```
start
for each position in sequence:
    kmer = sequence[position:position+k]
stop
```

$L-k+1$  kmers in a sequence

# Kmer spectra

# Kmer spectra

Counting Kmers is easy... anyone can count

- Count + compare
- Count + compare + sort

```
## Bash kmer counter as good as any other but slower  
head -n 4 pe_reads_R1.fastq | bioawk -c'fastx' '{for (x=0; x<length($seq)-11+1; ++x)print  
substr($seq, x, 11)}' | sort | uniq -c | awk '{print $1}' | sort -n | uniq -c
```

Any software that  
can count and  
compare is good

<https://github.com/TGAC/KAT>

A bit of kmer wrangling with KAT to get comfortable

# PhiX-174

5386 bp

Rendered using Bandage (Wick R.R. et al., Bioinformatics, 31(20), 3350-3352)

# Signatures in the spectra-cn

## Example: *A. thaliana* assembly

Total TAIR CDSs: 27,416

- In contigs: 27,079 (98.77%)
- Not in contigs: 337 (1.23%)
  - Paths found in paths: 175 (51.93%)
  - Most of the rest have paths, just more complex

# Heterozygosity

Random heterozygous genome 1

What structure is this going to produce in the graph.

How the heterozygosity is going to appear up in the spectra-cn

Is the structure of the graph going to affect the spectra-cn?

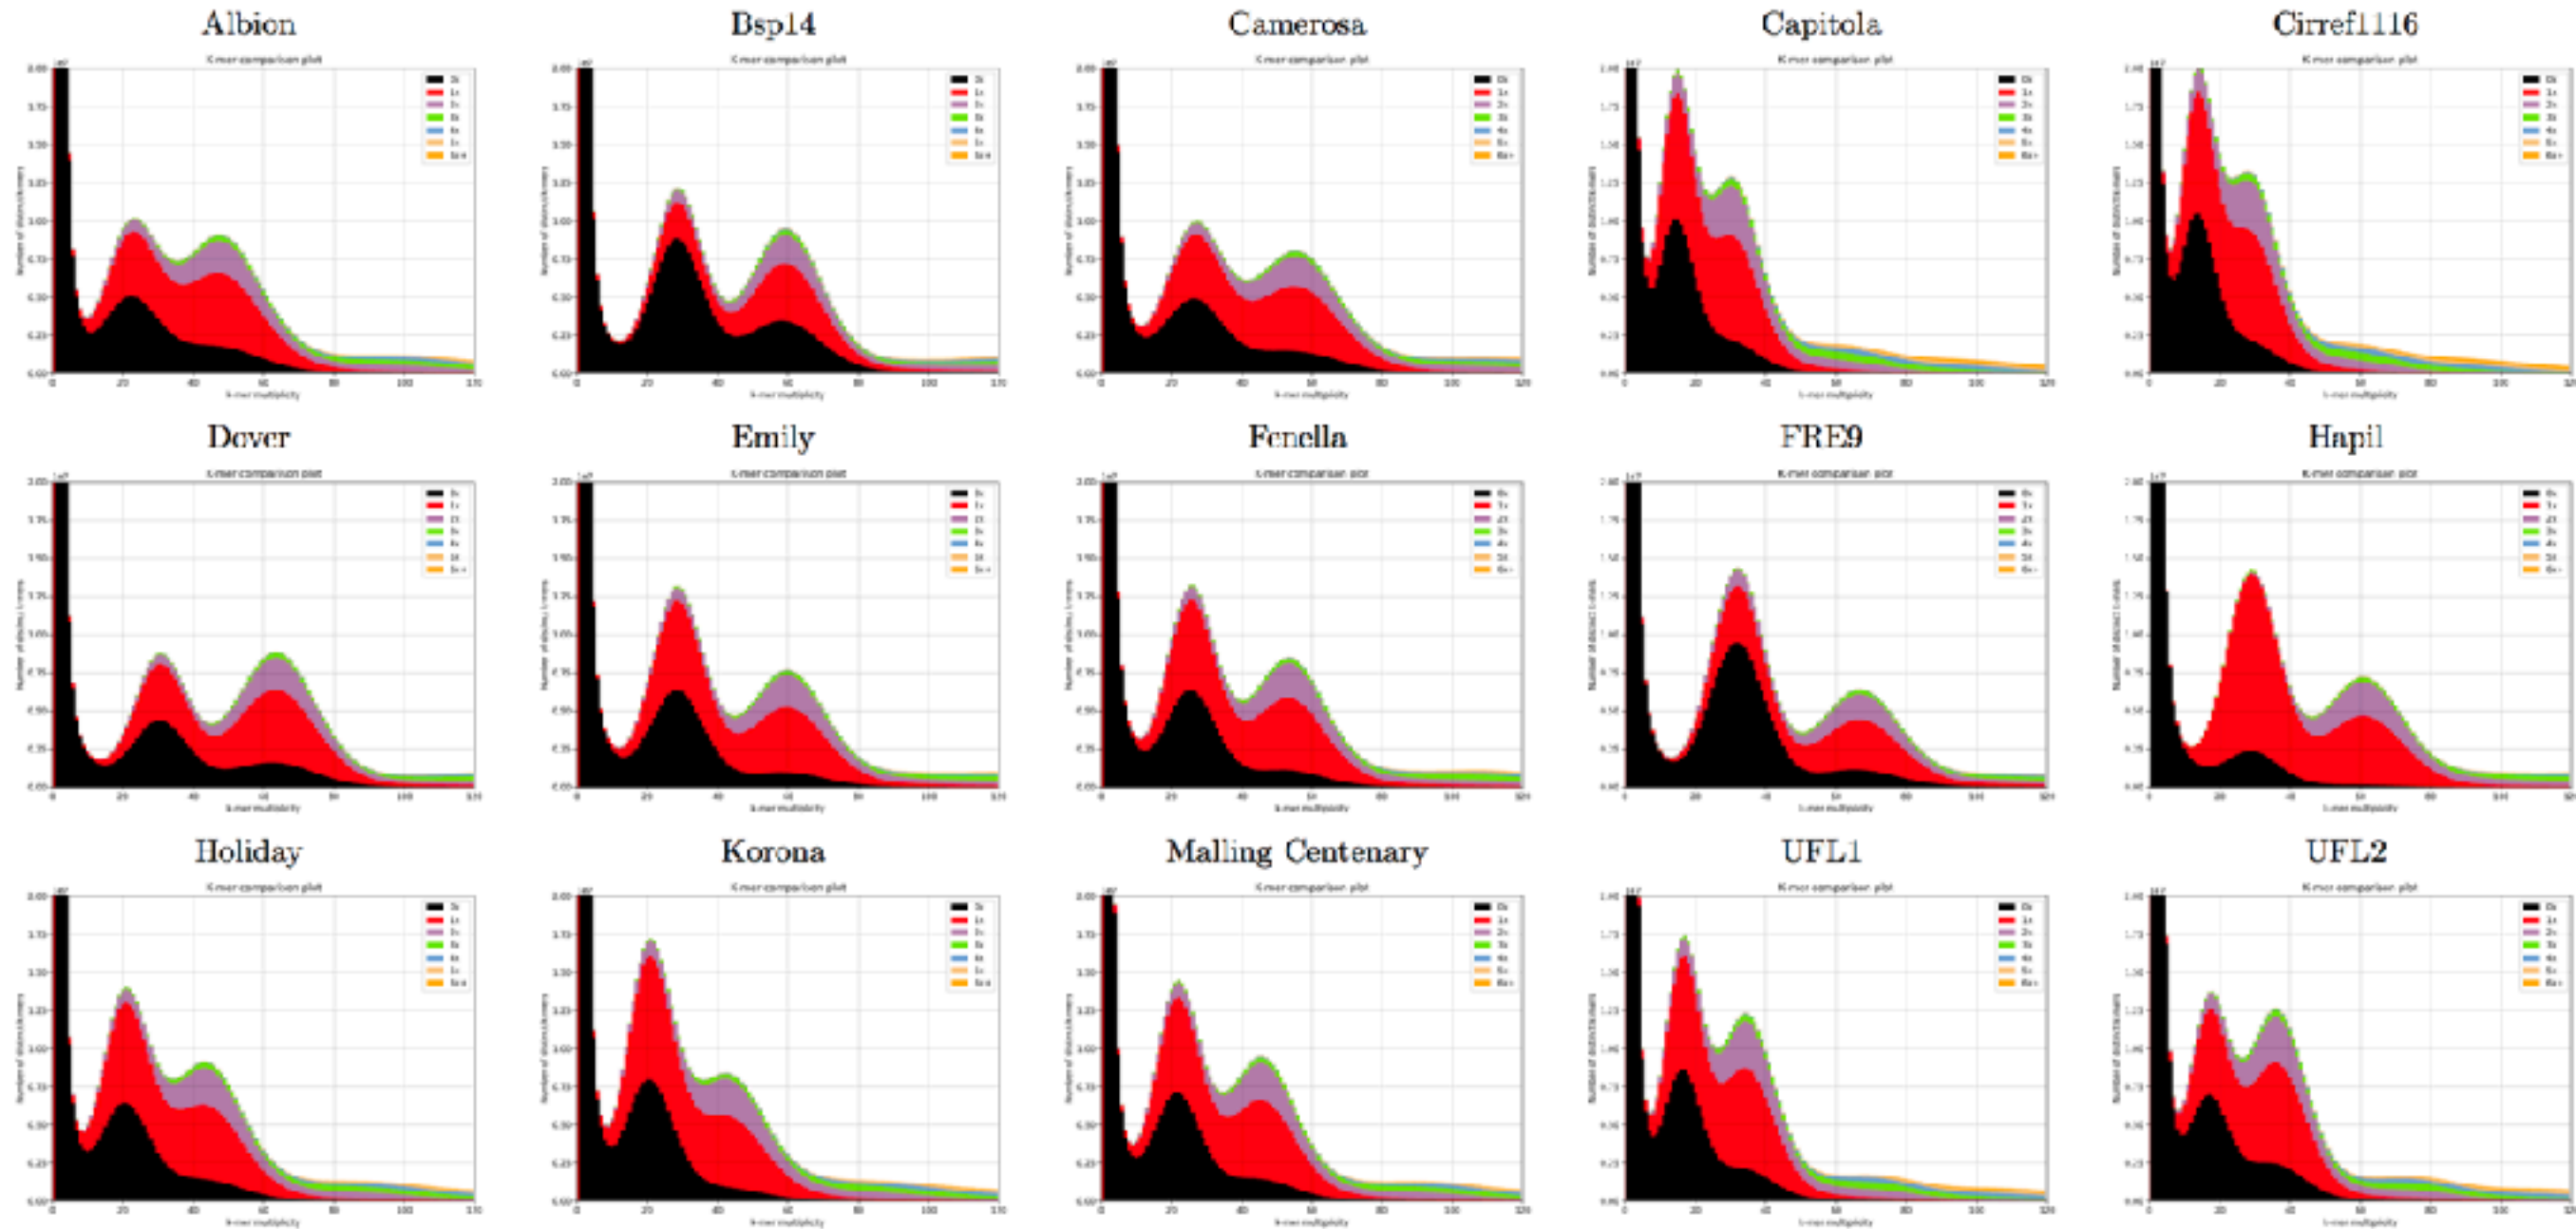

kat comp hetero\_1 vs reference

kat comp hetero\_1 vs abyss assembly

Kmer sources does not have to be from the same sample,

## 15 Strawberry cultivars (raw reads) vs Red Gauntlet (reference)

# Kat sect

Kat sect is a tool to project kmers from a kmer set on top of a sequence

Hetero\_1 example

kat sect pe vs scaffolds

kat sect scaffolds vs scaffolds

Blue pe vs scaffolds  
Red scaffolds vs self

# The 10x “lost SNPs tale”

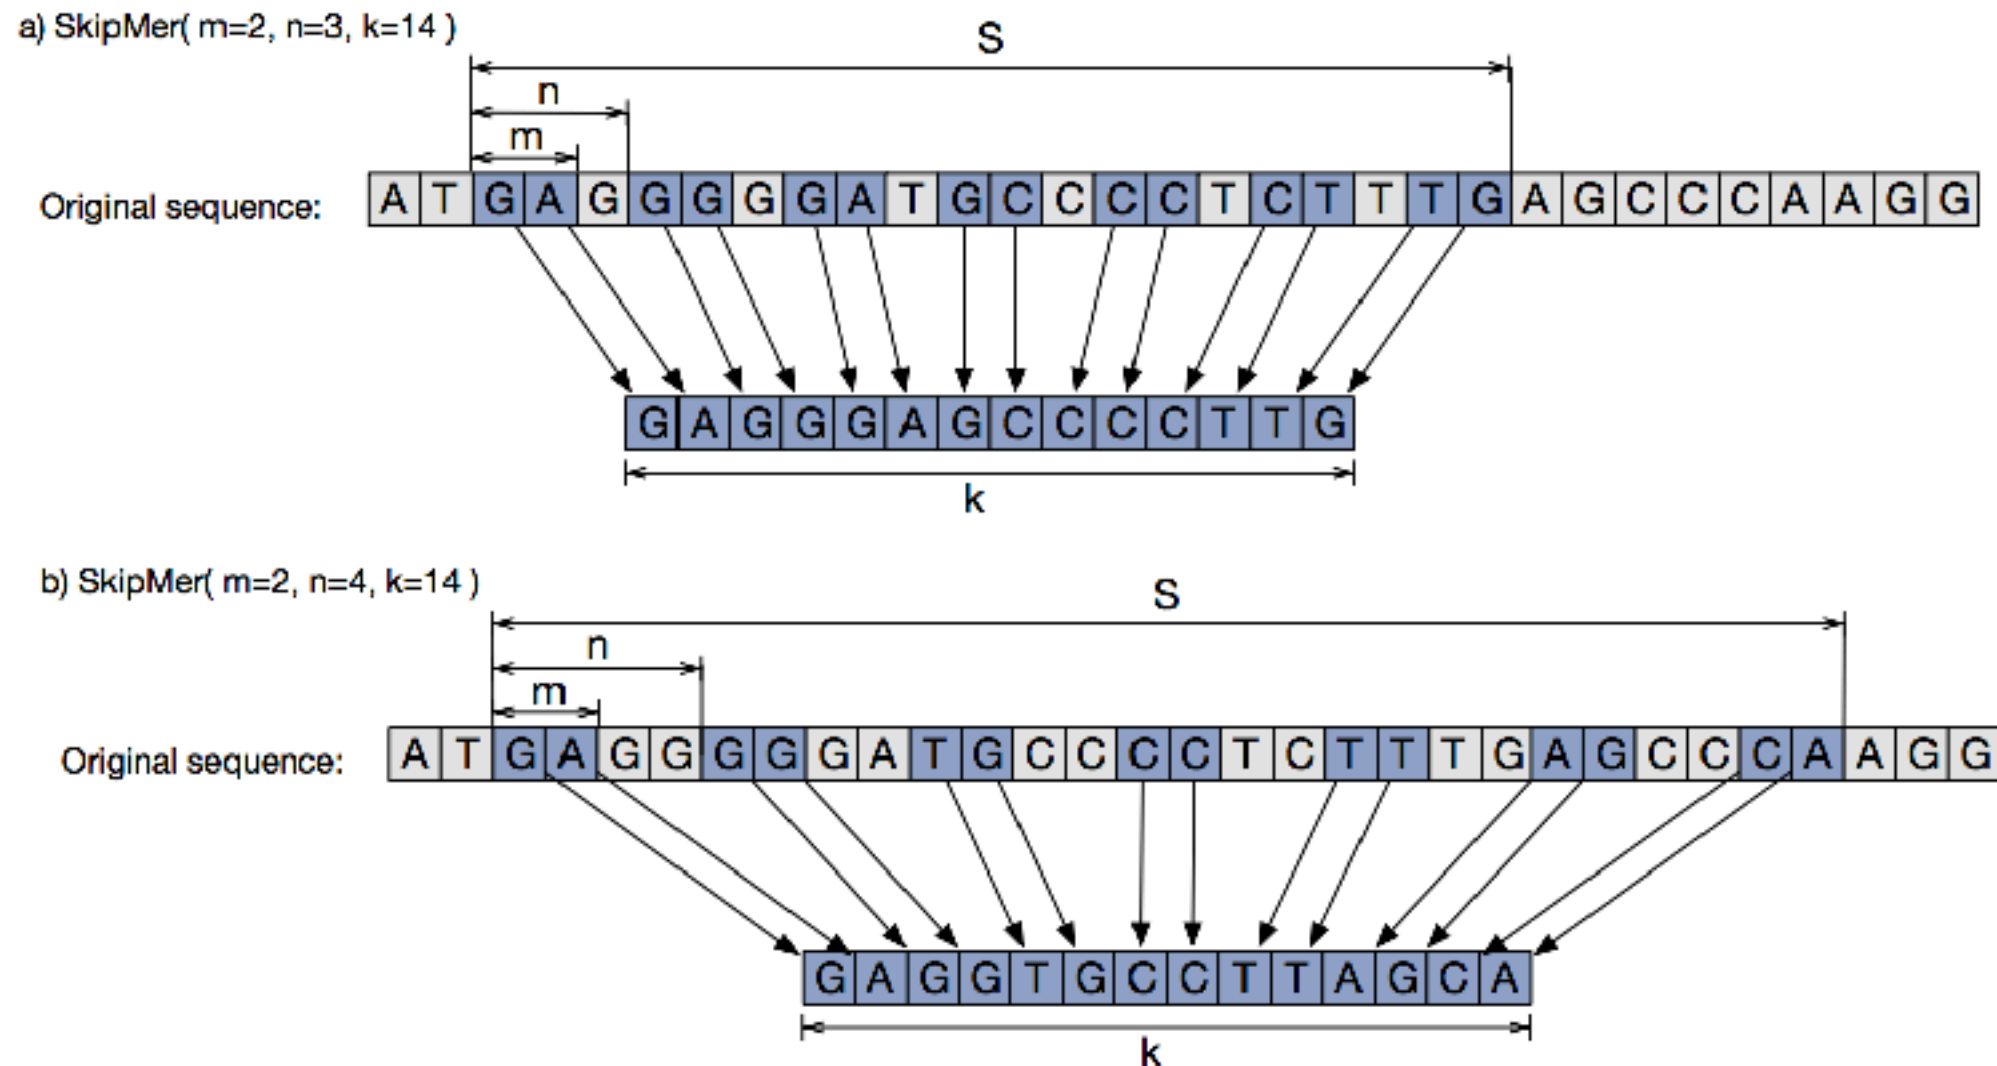

HGP: 21796

SNP No	Position on scaffold	PS1	PS2	10x reads variant	short read variant	w2rap assembly
1	24418	G	T	GT	GT	T
2	33101	A	T	AG	AG	A
3	3822	T	G	TG	TG	G
4	2179	A	A	AG	AG	A
5	17217	G	G	GA	GA	A
6	86982	T	T	TG	TG	T
7	94675	A	A	AT	AT	T
8	101651	C	C	CG	CG	G
9	160945	T	T	TC	TC	C
10	188553	C	C	CT	CT	C

# Skip-mers: higher entropy, higher sensitivity

**Figure 1.** Different  $SkipMer(m, n, k)$  cycles defined over the same sequence region, resulting in different combinations of bases. The shape of the underlying cyclic q-gram is defined by the variables  $m$  (used bases per cycle),  $n$  (cycle length), and  $k$  (total number of bases).

(a) 2-way: *Arabidopsis thaliana*  $\wedge$  *Oryza sativa*

(b) 3-way: *Arabidopsis thaliana*  $\wedge$  *Oryza sativa*  $\wedge$  *Brachypodium distachion*

(c) 2-way: *Homo sapiens*  $\wedge$  *Mus musculus*

(d) 3-way: *Homo sapiens*  $\wedge$  *Mus musculus*  $\wedge$  *Canis familiaris*

**Figure 3.** Effect of different combinations of  $m$  and  $n$ , while keeping  $k$  constant, for 2-way and 3-way skip-mer intersections. Only unique skip-mers are considered and skip-mers originating from sequence annotated with gene features on the first genome are classified as "In gene". The skip-mer shapes are sorted along the vertical axis according to total skip-mer span ( $S$ ), with the largest span on top.
